Story Title

QA | Load Testing for Nomination/Portfolio Flow to Handle 10k Entries

Description

text

The client has highlighted a potential high-volume scenario (150k nominations).

Current system performance under such load is unverified.

text

Objective:

strong

hardBreak

text

Perform load testing on the nomination and portfolio flow to confirm that the system can handle 150k entries efficiently.

Acceptance Criteria

text

System successfully processes 10k entries without critical failures.

text

Response times remain within acceptable thresholds (to be defined with product/tech team).

text

Detailed test report shared with stakeholders.

Additional Information

text

System successfully processes 10k entries without critical failures.

text

Response times remain within acceptable thresholds (to be defined with product/tech team).

text

Detailed test report shared with stakeholders.

Story Score

Overall quality score, improvement recommendations, and summary.

Overall Quality Score

80

Improvement Recommendations

User Story Evaluation

Parameter Scores

* **Clarity: 16/20**

The user story is generally easy to understand, but some parts of the description and acceptance criteria could be more concise and direct. The use of "text" and "strong" formatting in the description makes it slightly harder to read.

* **Completeness: 14/20**

The acceptance criteria are well-defined, but the preconditions for the load testing are not explicitly stated. The description mentions a high-volume scenario, but it would be helpful to have more context about the current system performance and the expected outcomes.

* **Business Value Alignment: 18/20**

The user story reflects tangible retailer value by ensuring the system can handle a large number of nominations efficiently, which is crucial for operational efficiency and consumer safety.

* **Testability: 17/20**

The acceptance criteria are specific and measurable, making it easy for QA engineers to derive test cases. However, the description could provide more details about the testing environment and the expected results.

* **Technical Feasibility: 15/20**

The user story is practically implementable, but it assumes that the system can handle 150k entries without critical failures. It would be helpful to have more information about the system's current capacity and any potential technical constraints.

Overall Quality Score: 80/100

Improvement Recommendations

* **Clarity:**

- + Remove unnecessary formatting in the description.
- + Use concise language to describe the objective and acceptance criteria.

* **Completeness:**

- + Add preconditions for the load testing, such as the current system performance and expected outcomes.
- + Provide more context about the high-volume scenario and its impact on the system.

* **Business Value Alignment:**

- + Emphasize the importance of operational efficiency and consumer safety in the description.
- + Consider adding more details about the benefits of load testing for the retailer.

* **Testability:**

- + Provide more details about the testing environment and expected results.
- + Consider adding more specific acceptance criteria, such as response times and error rates.

* **Technical Feasibility:**

- + Add more information about the system's current capacity and potential technical constraints.
- + Consider consulting with technical experts to ensure the user story is feasible and aligned with the system's capabilities.

<h3>Summary</h3>

The user story is well-structured and reflects tangible retailer value. However, it could benefit from more concise language, additional context, and more specific acceptance criteria. By addressing these areas, the user story can become more effective and efficient, reducing rework and aligning with digital retailer standards.

- Export Excel

Test Case ID	Title	Preconditions	Steps	Expected Results
LT-NOM-001	Baseline "Cold-Start" Load Test (10k nominations)	Test environment mirrors production (DB, API gateway,	- Start monitoring. - Execute the data-generator script to POST each nomination	All 10k nominations persist without any 5xx errors.

Test Case ID	Title	Preconditions	Steps	Expected Results
	submitted sequentially)	services). • Nomination data generator ready with 10k valid records. • Monitoring tools (CPU, memory, DB latency, response-time charts) are active.	one after another (no think-time). 3. After the last request, stop monitoring. 4. Export logs and response-time metrics.	• Average response time the three defined product ≤ 2 s). • No critical server-side exceptions. • Resource usage stays within limits (CPU < 70%, RAM < 70%, etc.).
LT-NOM-002	Gradual Ramp-Up Load Test (peak concurrency 200 users)	• Same environment as TC-001. • Load-testing tool (e.g., JMeter, Gatling) configured with a ramp-up schedule. • Acceptance threshold for max response time defined (e.g., ≤ 3 s).	1. Start monitoring. 2. Begin ramp-up: 0 → 200 virtual users over 5 min. 3. Each virtual user continuously submits nominations until a total of 10k requests is reached. 4. Capture response times, error rates, and system metrics. 5. Stop the test and collect logs.	• System processes 10k requests with error rate ≤ 1%. • 95th-percentile response time the defined threshold. • No database deadlocks or connection exhaustion. • CPU/memory spikes are transient and return to baseline within 2 min after load ends.
LT-NOM-003	Sustained Load Test (10k nominations over 30 min, constant 150 concurrent users)	• Environment as above. • Acceptance criteria for sustained throughput (e.g., ≥ 333 req/min).	1. Start monitoring. 2. Launch 150 virtual users that each submit a nomination every 5 seconds (steady-state). 3. Continue for 30 minutes (≈ 9k requests) then add a final burst of 1k	• Throughput remains stable: requests per second through 30-min test ≥ 333. • No increase in error rate or response time (stable ≤ 1%). • System resource usage remains within defined limits.

Test Case ID	Title	Preconditions	Steps	Expected Results
			requests to reach 10 k total. 4. Record throughput, latency, and any resource saturation.	within defined limits; no leaks or pauses • All 10k nominations stored correctly
LT-NOM-004	Peak-Concurrency Spike Test (10 k nominations with a sudden 1 000-user burst)	• Same baseline environment. • Spike-threshold for response time defined (e.g., ≤ 5 s for 99 % of requests).	1. Warm-up the system with 200 users for 2 min. 2. Immediately inject a spike of 1 000 additional users (total 1 200 concurrent) for 30 seconds, each sending a nomination request. 3. After the spike, return to the warm-up level for another 2 min. 4. Capture error rates, response-time distribution, and server metrics.	• System handles the spike without critical failures (error rate ≤ 1 %). • 99 % of requests completed within ≤ 5 s. • No request queue overflow or timeout. • All 10k nominations eventually persisted (including those sent during spike).
LT-NOM-005	Post-Test Reporting & Validation	• All previous test runs completed and logs collected. • Access to stakeholder reporting template.	1. Aggregate results from TC-001-004 (response-time charts, error-rate tables, resource-utilization graphs). 2. Verify data integrity: query the database to confirm exactly 10 k new nomination	• A comprehensive test report produced, containing: • Summary of each test metrics, pass/fail status. • Evidence that the system handled entries within critical f

Test Case ID	Title	Preconditions	Steps	Expected
			records with correct status. 3. Populate the load-test report (objective, methodology, findings, risks, recommendations). 4. Review the report with product/tech leads and obtain sign-off.	• Respons figures a agreed • Reconm for any c bottlene • Stakeh receive and forr acknowl accepta
